1 Introduction

> "Listening to the world. Well, I did that, and I still do it. I still do it." (Mary Oliver in Oliver and Tippett 2015)

This site contains materials for a workshop on multilevel modeling.

1.1 Background

Multilevel models are useful when you have data that are nested or clustered inside social units such as schools, neighborhoods, states, or countries.

Multilevel models are also useful when you have longitudinal data where repeated measures are collected for study participants.

> 💡 The Importance of Multilevel Models
>
> Multilevel models may improve one's statistical inferences in two important substantive ways.
>
> - Multilevel models adjust standard errors for clustering, and thus calculate appropriate p values. Failure to use a model that accounts for the clustering in the data may lead to improperly calculated standard errors and p values, possibly leading to false attributions of statistical significance (false positives) (see Chapter 2).
> - Multilevel models adjust regression coefficients (β's) for the presence of clustering. Failure to use a model that accounts for the clustering in the data may lead to improperly calculated regression coefficients (β's) which may have the wrong magnitude, the wrong statistical significance, and even the wrong sign (see Chapter 3).

1.2 Simulated Multilevel Data

The data used in these workshop materials are *simulated* data on parents, children and families. The data are simulated to come from 30 hypothetical countries around the world. These are the same data used and discussed in my book *Multilevel Thinking: Discovering Variation, Universals, and Particulars in Cross-Cultural Research*.

There are two versions of the data: a *cross-sectional* data set from a single point in time; a *longitudinal* version of the data spanning several time points.

> **i** The Data Can Be Downloaded Here:
>
> - Cross Sectional Data
> - Longitudinal Data

Table 1.1: Variables in Simulated Multilevel Data

pos	variable	label
1	country	country id
2	HDI	Human Development Index
3	family	family id
4	id	unique country family id
5	identity	hypothetical identity group variable
6	intervention	recieved intervention
7	physical_punishment	physical punishment in past week
8	warmth	parental warmth in past week
9	outcome	beneficial outcome

Table 1.2: Sample Data From Simulated Multilevel Data

country	HDI	family	id	identity	intervention	physical_punishment	warmth	outcome
15	77	59	15.59	0	0	3	6	57.13
2	83	49	2.49	0	1	3	4	57.51
16	57	50	16.50	1	0	1	5	51
24	82	38	24.38	0	0	1	6	59.41
28	53	32	28.32	0	0	5	2	45.1

2 The Importance of Accounting for Clustered Data

2.1 Grouped and Individual Data

Bland and Altman (1994) suggested the following procedure for simulating some data:
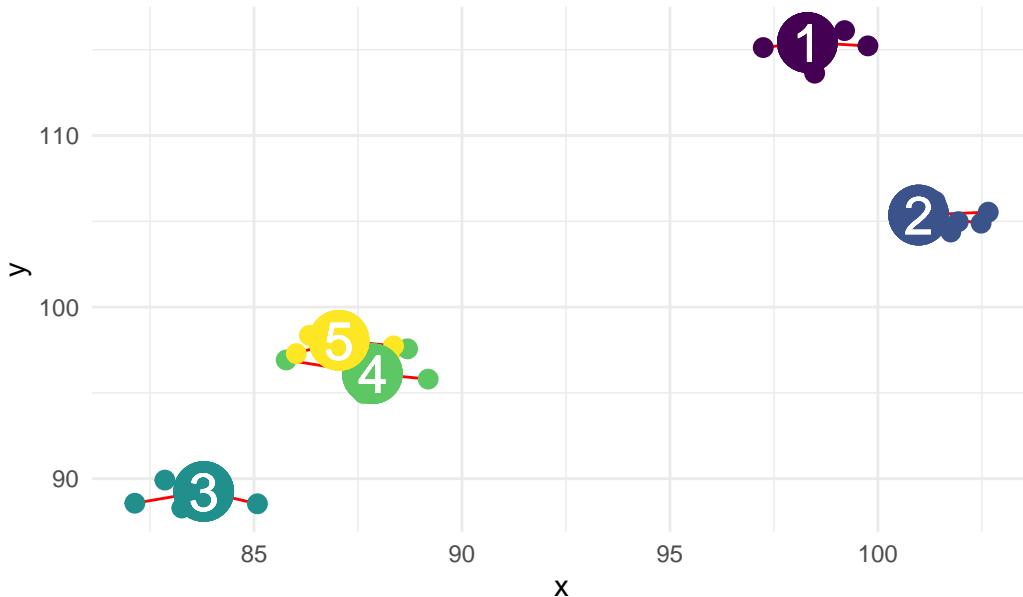

> "The data were generated from random numbers, and there is no relation between X and Y at all. Firstly, values of X and Y were generated for each 'subject,' then a further random number was added to make the individual observation." (Bland and Altman 1994)

So… we follow their procedure.

> **i** Simulating The Data
>
> The graph below illustrates the process of simulating the data.

Illustrating the Process of Simulating Clustered Data

2.2 Analyses

2.2.1 OLS

An OLS analysis indicates that there is a statistically significant association of x and y.

```
                         OLS1
-------------------------------
x_individual            1.046 **
Intercept               4.488
Number of observations    25
-------------------------------
** p<.01, * p<.05
```

2.2.2 MLM

In contrast, an MLM analysis (correctly) finds that there is no statistically significant association of x and y.

```
                        MLM1
-------------------------------
x_individual            0.039
Intercept              97.005 **
var(_cons)             74.523
var(e)                  0.594
Number of observations    25
-------------------------------
** p<.01, * p<.05
```

2.2.3 Compare OLS and MLM

```
                      OLS1        MLM1
-----------------------------------------
x_individual        1.046 **   0.039
Intercept           4.488     97.005 **
var(_cons)                     74.523
var(e)                          0.594
Number of observations   25        25
-----------------------------------------
** p<.01, * p<.05
```

3 Estimation of β Coefficients

3.1 Introduction
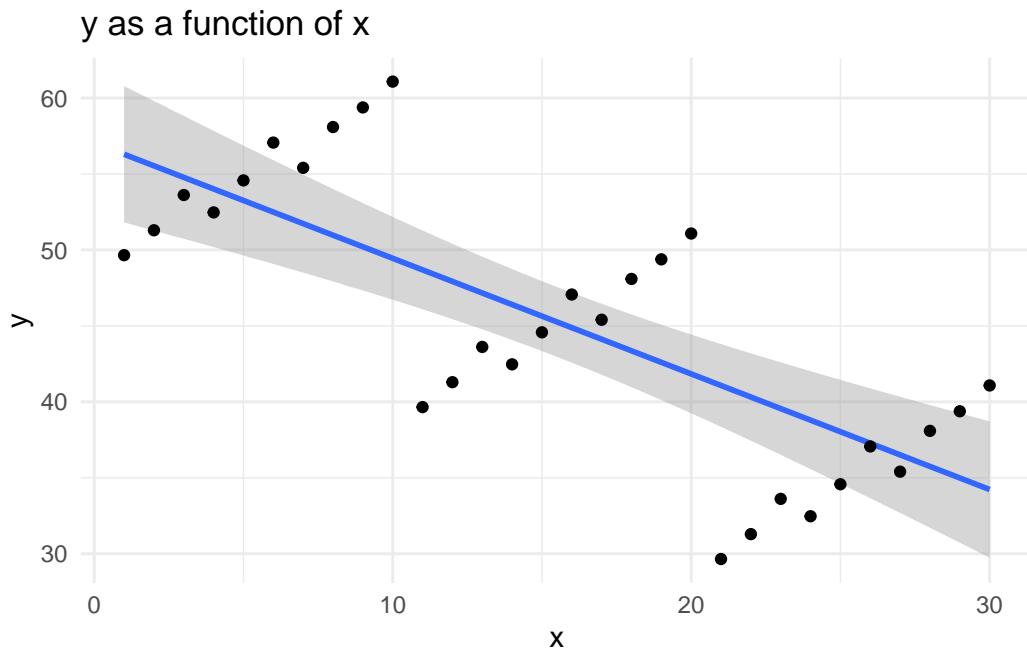

Associations between two variables can be *very different* (or even *reversed*) depending upon whether or not the analysis is "aware" of the grouped, nested, or clustered nature of the data (Nieuwenhuis 2015; Diez Roux 2003; Gelman et al. 2007). In multilevel analysis, the groups are often schools, neighborhoods, communities, or countries.

A model that is "aware" of the clustered nature of the data may provide very different–likely better–substantive conclusions than a model that is not aware of the clustered nature of the data. This phenomena is closely related to the "ecological fallacy": the idea that group level and individual level relationships are not necessarily the same (Firebaugh 2001).

3.2 Graphs
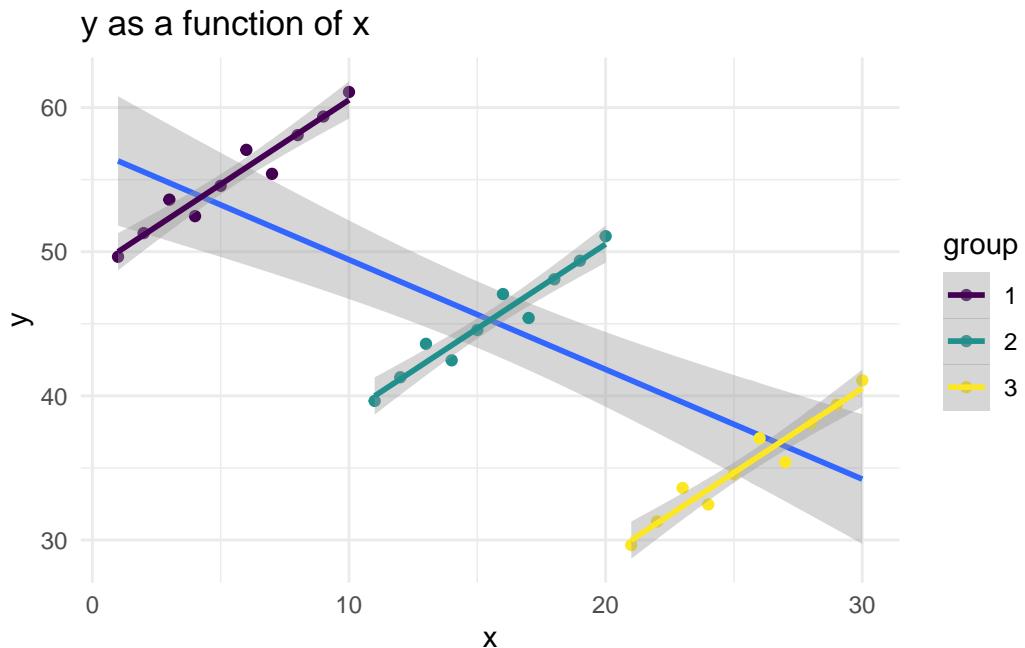

3.2.1 A "Naive" Graph

This "naive" graph is unaware of the grouped nature of the data.

y as a function of x

3.2.2 An "Aware" Graph

This "aware" graph is aware of the grouped nature of the data.

y as a function of x

3.3 Regressions

3.3.1 A "Naive" OLS Analysis

The OLS model with only x as a covariate is not aware of the grouped structure of the data, and the coefficient for x reflects this.

```
                              OLS2
------------------------------
x                       -0.761 **
Intercept               57.057 **
Number of observations     30
------------------------------
** p<.01, * p<.05
```

3.3.2 An "Aware" MLM Analysis

The multilevel model is aware of the grouped structure of the data, and the coefficient for x reflects this.

```
                              MLM2
------------------------------
x                        1.166 **
Intercept               27.192 **
var(_cons)             312.623
var(e)                  0.806
Number of observations     30
------------------------------
** p<.01, * p<.05
```

3.3.3 Compare The Models

```
                              OLS2       MLM2
------------------------------------------
x                       -0.761 **   1.166 **
Intercept               57.057 **  27.192 **
var(_cons)                        312.623
var(e)                              0.806
Number of observations     30         30
------------------------------------------
** p<.01, * p<.05
```

3.4 A Thought Experiment
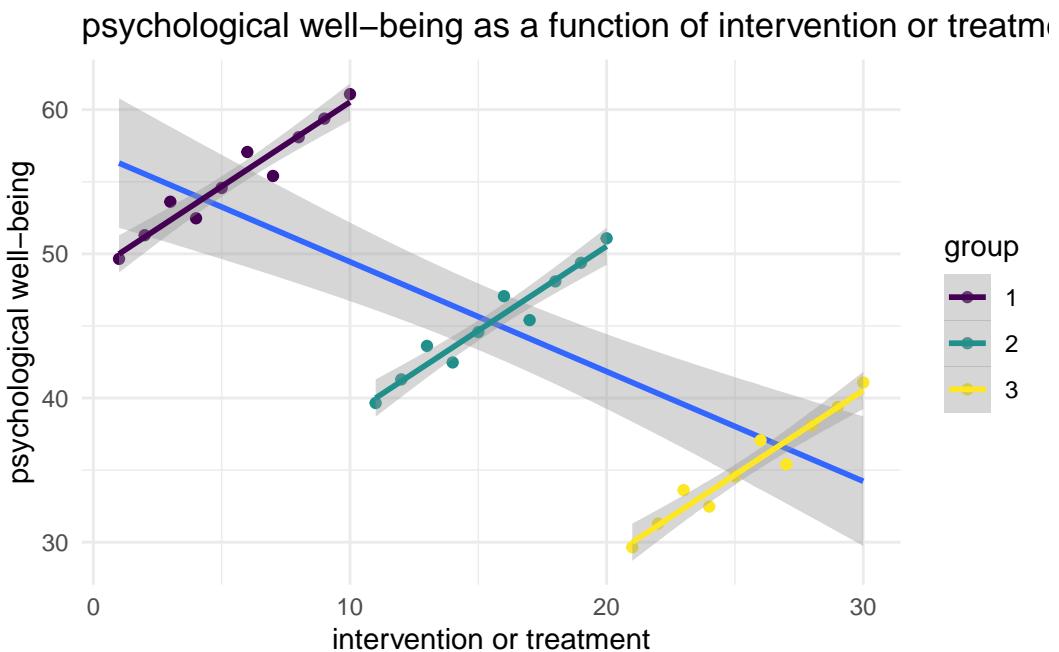

When might a situation like this arise in practice? This is surprisingly difficult to think through.

Imagine that x is a protective factor, or an intervention or treatment. Imagine that y is a desirable outcome, like improved mental health or psychological well being.

Now imagine that people provide more of the protective factor or more of the intervention in communities where there are lower levels of the desirable outcome. If we think about it, this is a very plausible situation.

> 💡 A Naive Analysis Would Misconstrue The Results
>
> A naive analysis that was unaware of the grouped nature of the data would therefore misconstrue the results, suggesting that the intervention was harmful, when it was in fact helpful.

These data are constructed to provide this kind of extreme example, but it easy to see how multilevel analysis may provide better answers than we would get if we ignored the grouped nature of the data.

4 Two Level Cross Sectional; And Three Level Longitudinal Models

4.1 Cross Sectional Model

4.1.1 Get Data

```
use "simulated_multilevel_data.dta", clear
```

4.1.2 The Equation

$$\text{outcome}_{ij} = \beta_0 + \beta_1 \text{parental warmth} + \beta_2 \text{physical punishment} + \beta_3 \text{time} +$$

$$\beta_4 \text{identity}_2 + \beta_5 \text{intervention} + \beta_6 HDI +$$

$$u_{0j} + u_{1j} \times \text{parental warmth} + e_{ij}$$

4.1.3 Descriptive Statistics

```
summarize // descriptive statistics
```

```
    Variable |        Obs        Mean    Std. dev.         Min         Max

4.4 QUESTIONS???

5 Cross-Classified Models

5.1 Introduction

A two level multilevel model imagines that *Level 1* units are nested in *Level 2* units. A three level multilevel model imagines that *Level 1* units are nested in *Level 2* units, which are in turn nested in *Level 3* units.

A cross-classified model imagines that the nesting is not hierarchical, but rather that there are two sets of clusters or nestings which overlap, but are not hierarchical.

5.2 Get Data

```
use "simulated_multilevel_longitudinal_data.dta", clear
```

5.3 Cross Classified Model

We can treat these random effects as being *cross classified*.

This might be useful if we had data where individuals lived in different countries at different times.

However, because `id` is in fact nested inside `country`, in this case, estimating the random effects as cross classified will be more time consuming, but will give us equivalent results to a three level model.

5.3.1 Standard (Less Computationally Efficient) Syntax

The below syntax will take a very long time to run with the full sample, and thus we have commented it out.

```
* mixed outcome t warmth physical_punishment || _all: R.country || _all: R.id

* est store crossed1
```

The documentation notes that we can use a *much* more computationally efficient version of the above command, which is what we do in these notes. The user can verify that both versions of the command will produce equivalent results.

In fact, at the end of handout we verify the similarity of both sets of syntax using a random sample.

5.3.2 Cross Classified With Computationally Efficient Syntax

```
mixed outcome t warmth physical_punishment || _all: R.country || id:

est store crossed2 // store crossed effects result
